

GETTING STARTED WITH NEUROPH

This guide gives you a brief overview on how to use *Neuroph* framework **version 2.8**

CONTENTS

1. What is Neuroph?
2. Whats in Neuroph?
3. Requirements
4. Installation and starting
5. Training neural network with Neuroph Studio
6. Creating Neural Networks in Java code with Neuroph
7. Web Links

1. What is Neuroph?

Neuroph is Java framework for neural network development.

2. Whats in Neuroph?

Neuroph consists of the Java library and GUI neural network editor called Neuroph Studio.

You can experiment with common neural network architectures in Neuroph Studio, and then use Neuroph Java library to use those neural networks in your Java programs.

3. Requirements

In order to use/run *Neuroph* you just need Java VM 1.7 installed on your computer. Everything else is provided in downloaded package.

4. Installation and Starting

To install NeurophStudio just start the installer wizard (neurophstudio-windows.exe for windows or neurophstudio-linux.sh for linux) and follow the simple wizard steps. For Mac unpack neurophstudio.zip.

Neuroph framework doesnt needs any specific installation procedure, just add reference to *neuroph-core-xx.jar* library to your Java project (and any other required jars like neuroph-imgrec-x.x.jar if you're using image recognition etc.) .

5. Training neural network with NeurophStudio application

Now we'll explain how to use NeurophStudio to create neural networks. There are 5 steps for training NN, and they will be described with example Perceptron neural network for logical OR function (V).

To create and train Perceptron neural network using Neuroph Studio do the following:

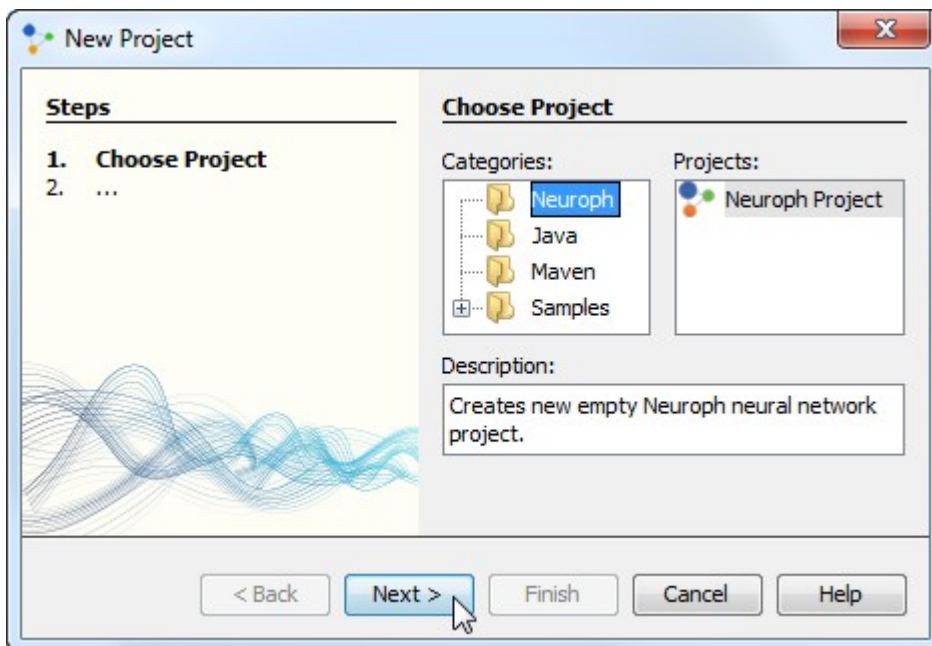

1. Create Neuroph Project.
2. Create Perceptron network.
3. Create training set (in main menu choose File > New > Data Set).
4. Train network
5. Test trained network

Step 1. Create Neuroph project.

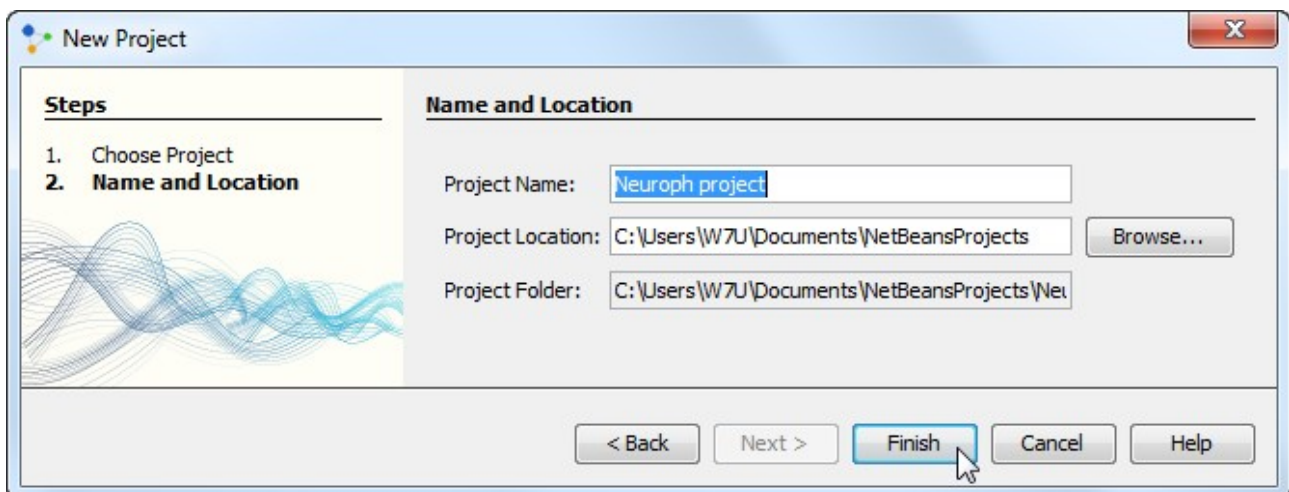

Click File > New Project.

Then, select Neuroph Project and click Next.

Enter project name and location, click Finish.

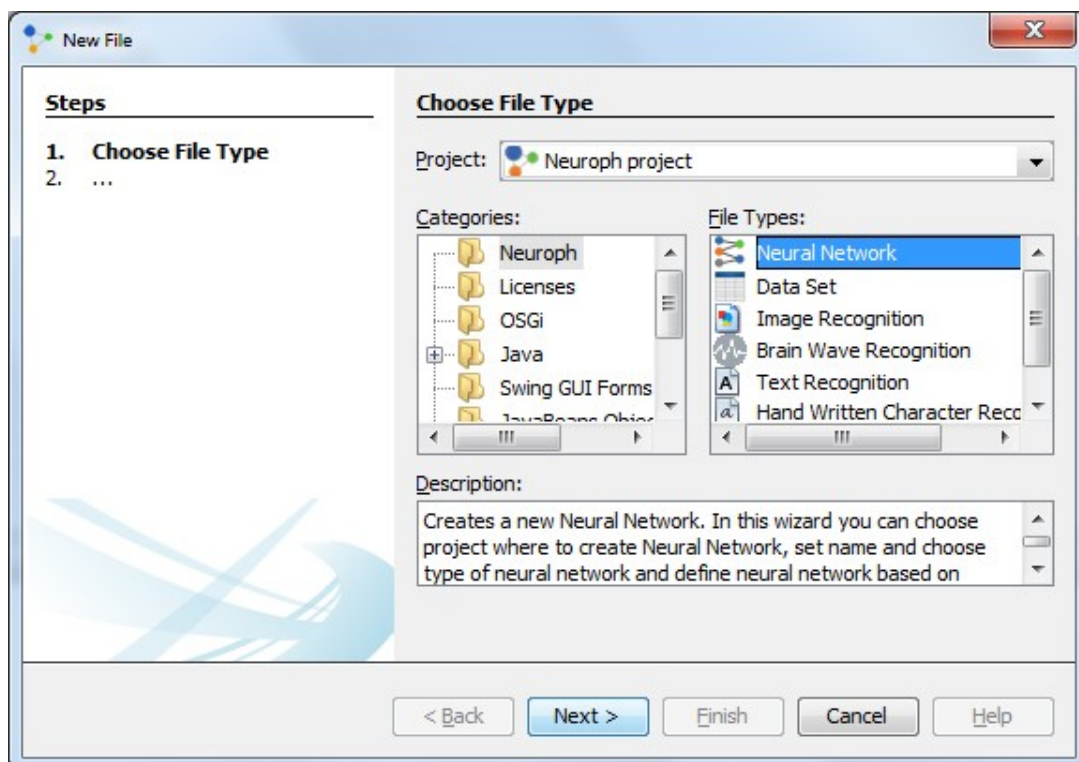

Project is created, now create neural network.

Step 2. Create Perceptron network.

Click File > New File

Select desired project from Project drop-down menu, Neuroph as category, Neural Network file type and click next.

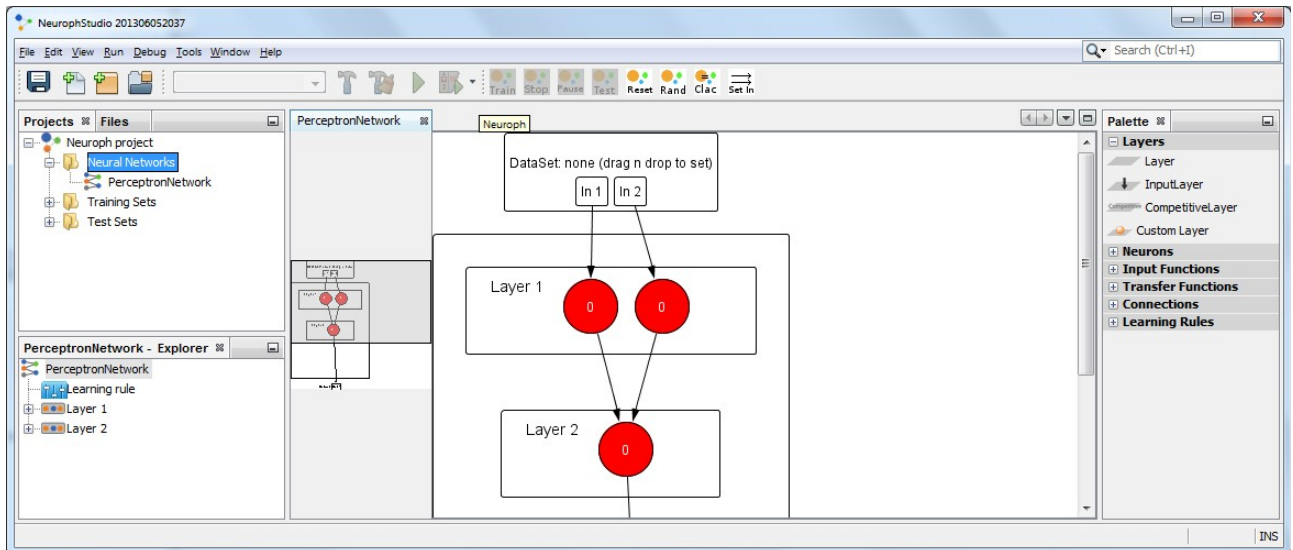

Enter network name, select Perceptron network type, click next.

The screenshot shows a 'New File' dialog box with a sidebar on the left and a main panel on the right. The sidebar, titled 'Steps', lists three steps: 1. Choose File Type, 2. Set neural network name and type (which is highlighted), and 3. Set network specific settings. Below the list is a diagram of a neural network with three nodes (blue, green, and orange) connected in a triangular pattern. The main panel, titled 'Set neural network name and type', contains a text field for 'Neural Network Name' with the value 'PerceptronNetwork'. Below this is a list box for 'Neural Network Type' with the following options: Adaline, Perceptron (selected), Multi Layer Perceptron, Hopfield, BAM, and Kohonen. At the bottom of the dialog are five buttons: '< Back', 'Next >' (with a mouse cursor over it), 'Finish', 'Cancel', and 'Help'.

In new perceptron dialog enter number of neurons in input (2) and output layer (1) , choose Perceptron Learning and click Create button.

The screenshot shows the same 'New File' dialog box, but now on Step 3: Number of input neurons, number of output neurons and learning rule. The sidebar still shows the same three steps, with Step 3 highlighted. The main panel contains three input fields: 'Inputs Num' with the value '2', 'Outputs Num' with the value '1', and a dropdown menu for 'Learning rule' set to 'Perceptron Learning'. At the bottom are five buttons: '< Back', 'Next >', 'Finish' (with a mouse cursor over it), 'Cancel', and 'Help'.

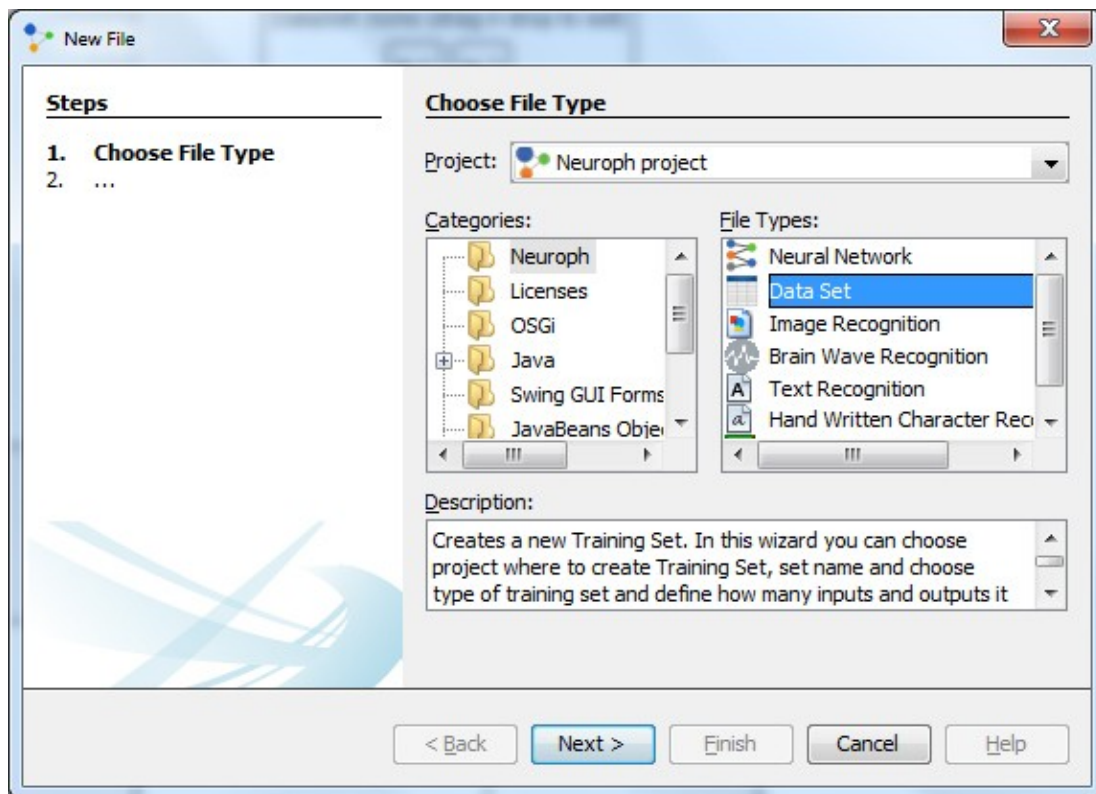

This will create the Perceptron neural network with two neurons in input, and one in output layer, all with Step transfer functions.

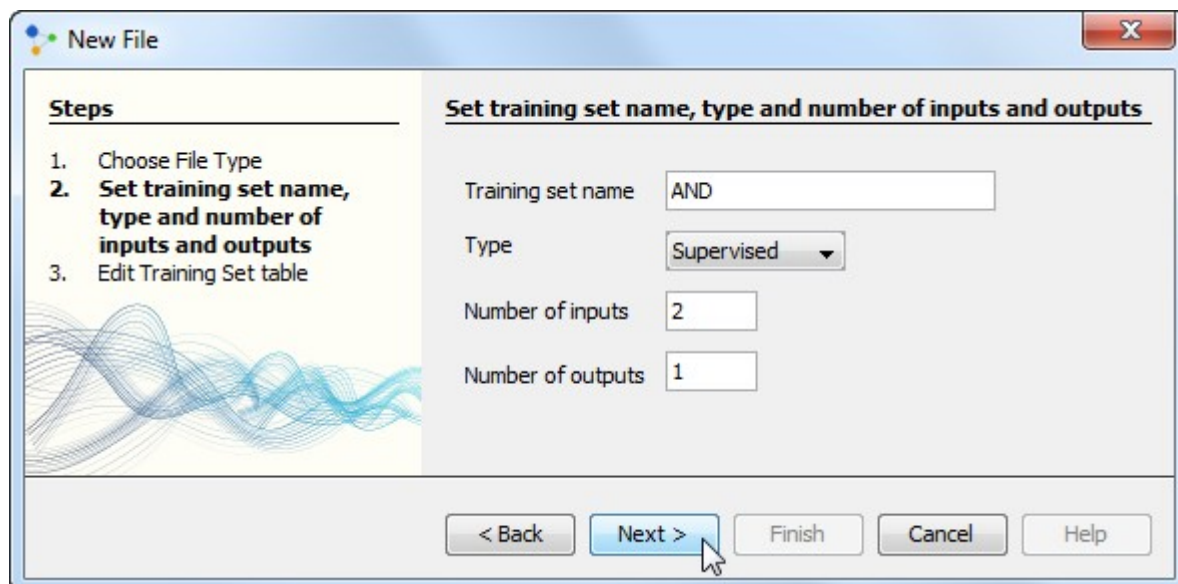

Step 3. To create training set, click File >New File to open training set wizard.

Select Data Set set file type, then click next.

Enter training set name, number of inputs and outputs as shown on picture below and click Create button.

Then create training set by entering training elements as input and desired output values of neurons in input and output layer. Use Add row button to add new elements, and click OK button when finished.

Steps

1. Choose File Type
2. Set training set name, type and number of inputs and outputs
3. **Edit Training Set table**

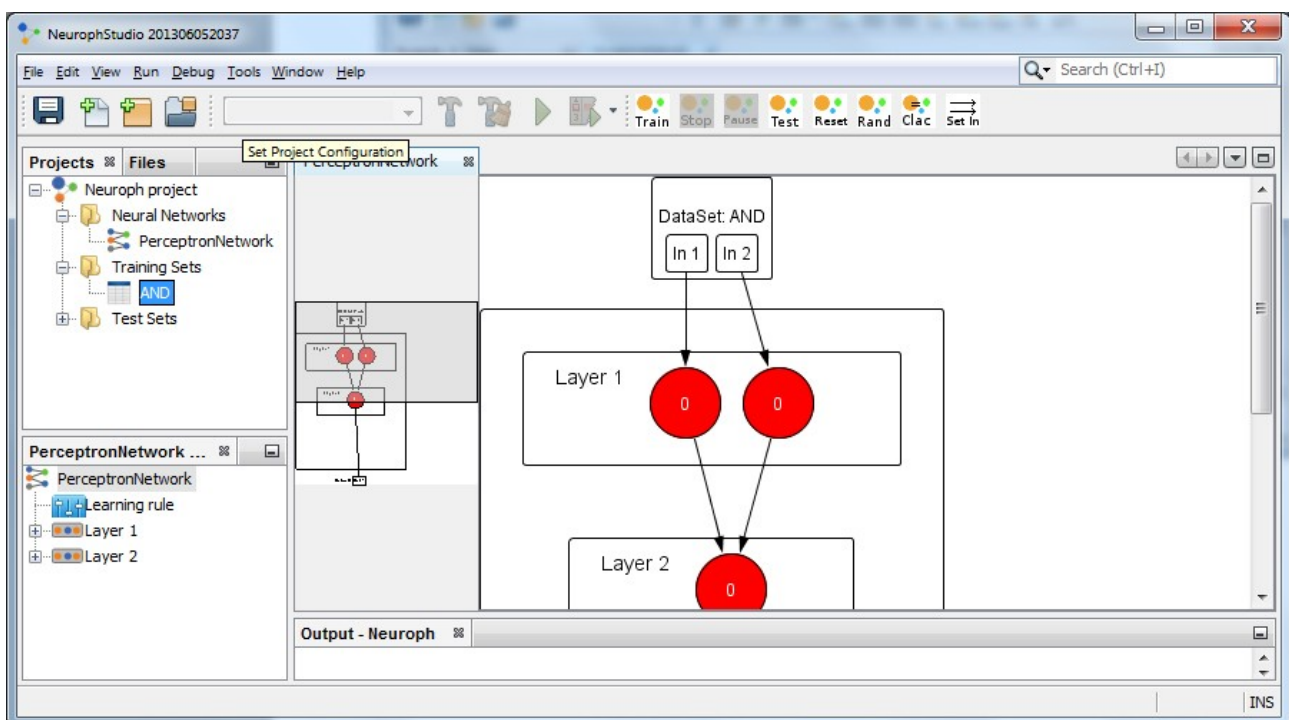

Edit Training Set table

Training Set Name: AND

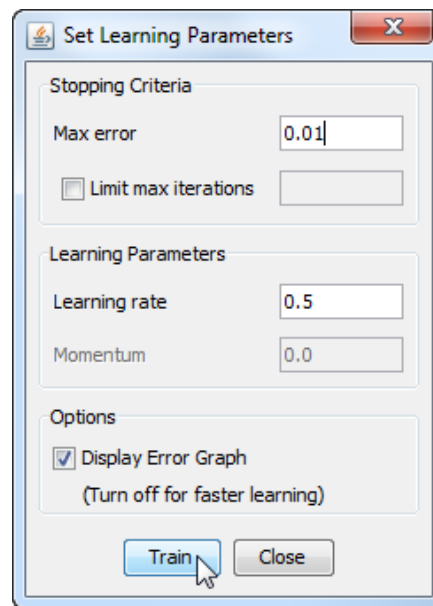

Input 1	Input 2	Output 1
0	0	0
0	1	0
1	0	0
1	1	1

< Back Next > **Finish** Cancel Help

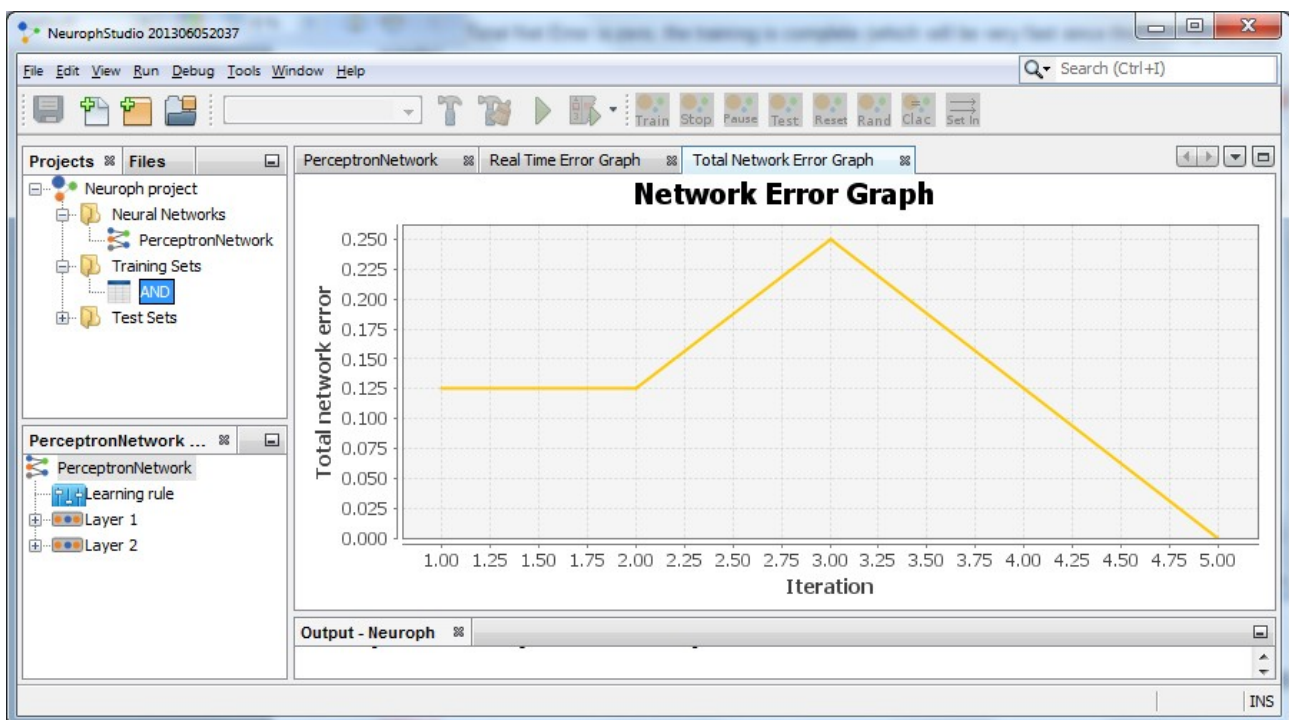

Step 4. Training the network. To set training set, drag created data set from project tree and drop it on data set component, and click Train button on toolbar.

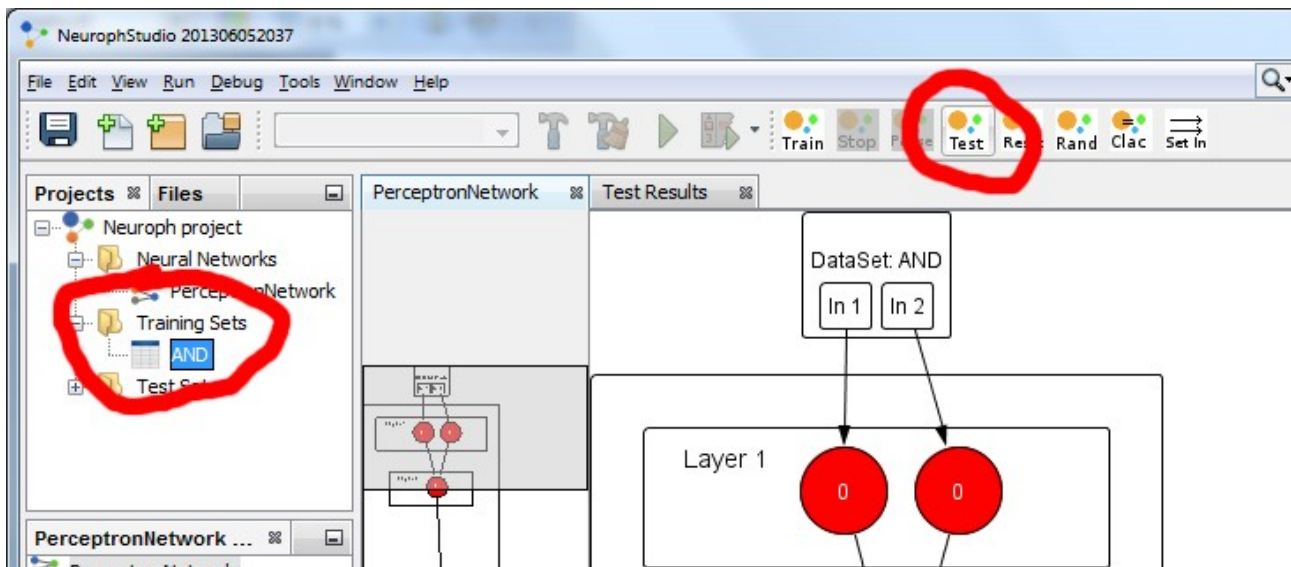

In Set Learning parameters dialog use default learning parameters, and just click the Train button.

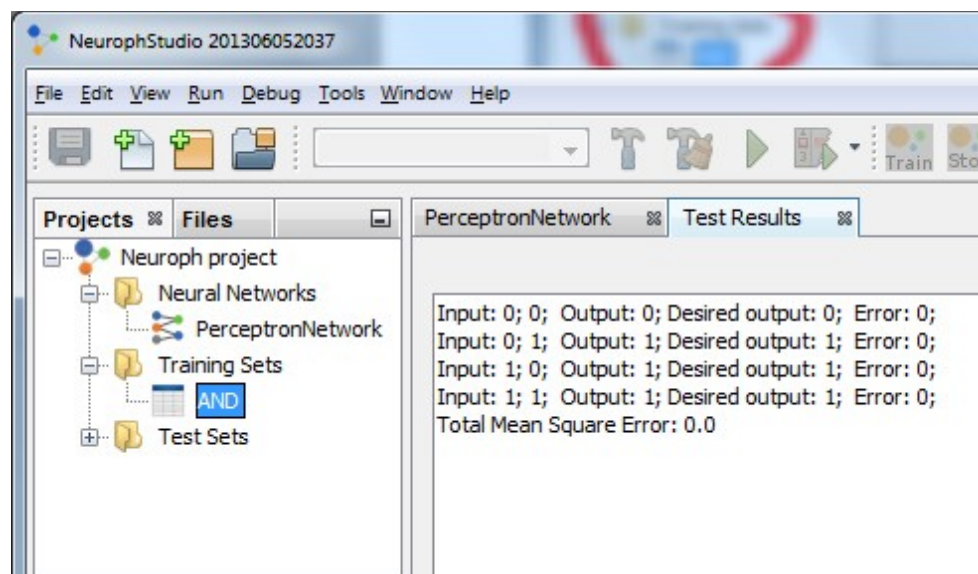

When the Total Net Error is zero, the training is complete (which will be very fast since this example is very simple)

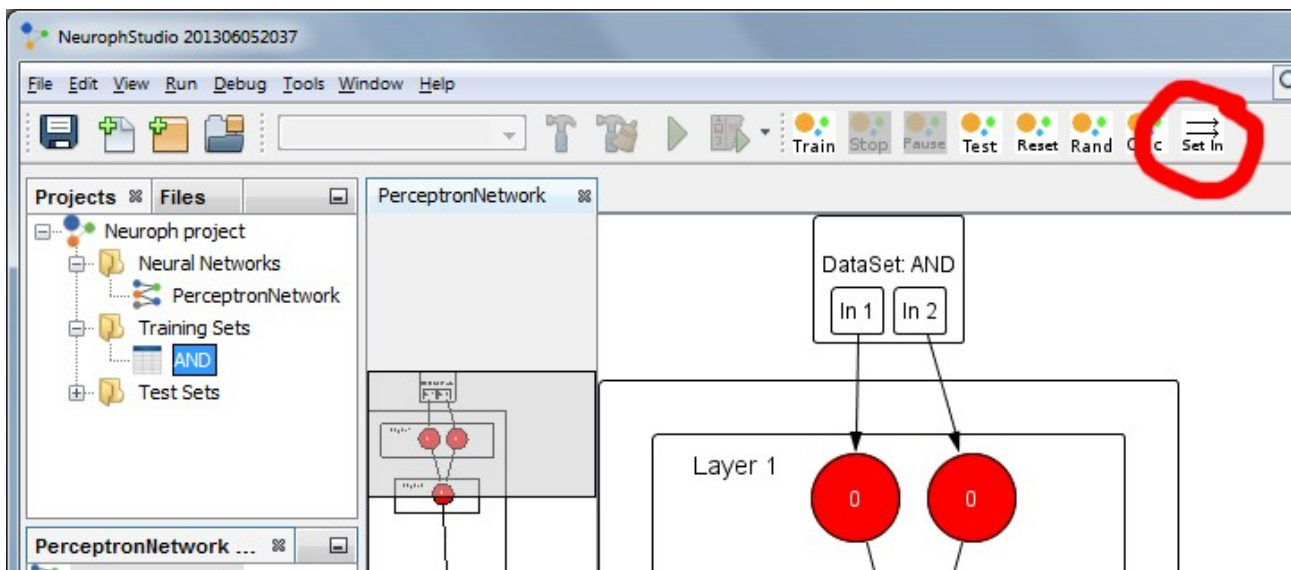

Step 5. After the training is complete, you can test the network for the selected data set by clicking Test button on toolbar.

This will open test results in a new tab.

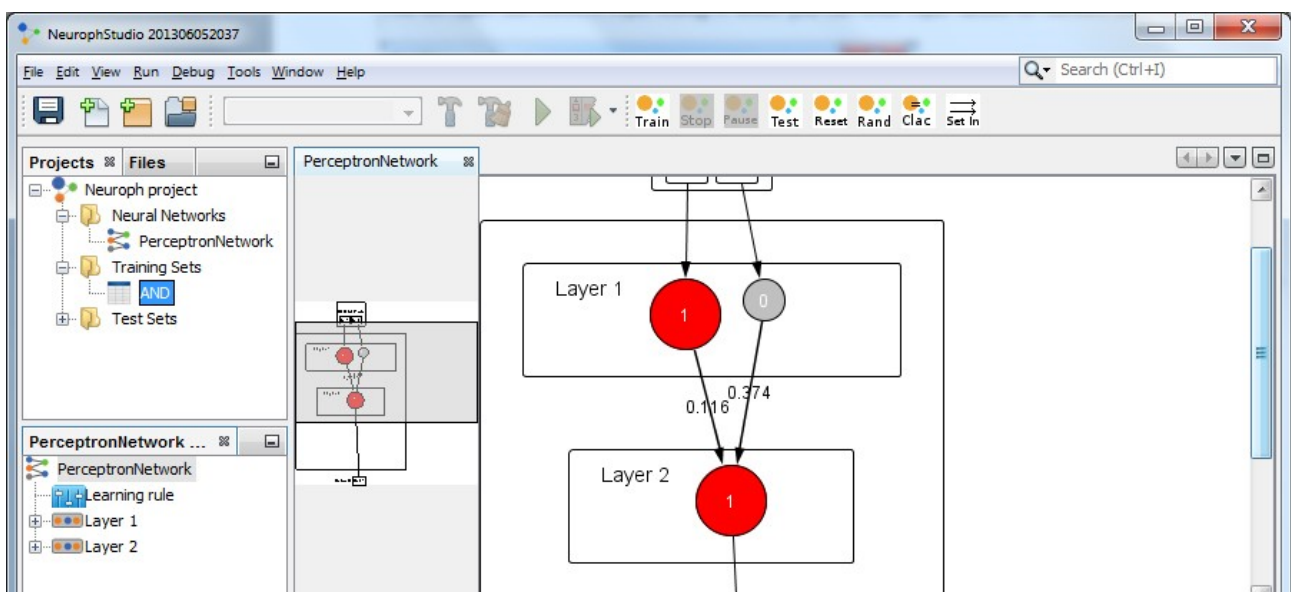

To test single input, use Set Input button.

This will open Set Network Input dialog in which you can enter input values for network delimited with space.

The result of network test is shown on picture below. Network learned logical AND function. As we can see the output neuron has value 0. Test the network to see how it behaves for other input values.

To set network display options use Right Click Menu > Display Preferences

6. Creating Neural Networks in Java code with Neuroph

This is the same example as in previous chapter, but now in Java code. Here is how to create, train and save Perceptron neural network with *Neuroph*:

```
// create new perceptron network
NeuralNetwork neuralNetwork = new Perceptron(2, 1);

// create training set
DataSet trainingSet =
    new DataSet(2, 1);
// add training data to training set (logical AND function)
trainingSet.addRow (new DataSetRow (new double[]{0, 0},
                                     new double[]{0}));
trainingSet.addRow (new DataSetRow (new double[]{0, 1},
                                     new double[]{0}));
trainingSet.addRow (new DataSetRow (new double[]{1, 0},
                                     new double[]{0}));
trainingSet.addRow (new DataSetRow (new double[]{1, 1},
                                     new double[]{1}));

// learn the training set
neuralNetwork.learn(trainingSet);

// save the trained network into file
neuralNetwork.save("and_perceptron.nnet");
```

The following example shows how to use saved network.

```
// load the saved network
NeuralNetwork neuralNetwork =
    NeuralNetwork.createFromFile("and_perceptron.nnet");

// set network input
neuralNetwork.setInput(1, 1);

// calculate network
neuralNetwork.calculate();

// get network output
double[] networkOutput = neuralNetwork.getOutput();
```

This example show the basic usage of neural network created with *Neuroph*.

To be able to use this in your programs, you must provide a reference to Neuroph Library jar file *neuroph-core-xx.jar* in your project (in NetBeans right click project, then Properties > Libraries > Add JAR/Folder, and choose jars). Also you must import the corresponding classes/packages, like *org.neuroph.core*, *org.neuroph.core.learning* and *org.neuroph.nnet*.

For more examples see source code in ***org.neuroph.samples*** package (which is located under Samples Maven project module) and **Help in NeurophStudio**.

List of all supported NN architectures, is available in *Neuroph* API documentation (see ***org.neuroph.nnet*** package).
